

Can an optical module with too high a luminous power still be used

Overview

If the received light level is too high for the detector in an active node, the result of overdriving the detector can cause noise in the signal, or worse case even damage to the unit. Overload optical power, also known as saturated optical power, refers to the maximum average input optical power that can be received by the receiver of an optical module under a certain bit error rate (BER, which is usually 10^{-12}). Note that the photodetector will have saturated. A constant trend in optical modules is to offer higher data rates within the size-limited and thermally-limited form factor by using smaller, integrated Power and Data-Converter solutions. Attenuators. For example, an LED module with 150 lm/W generates a total of 1500 lumens of luminous flux with a power consumption of 10 watts. The higher this value is, the more efficient the light source is.
