

Core Switch Backplane Bandwidth melgo

Overview

If you want to realize the full-duplex non-blocking transmission of the network, you must meet the minimum backplane bandwidth requirements. Calculated as follows $\text{Backplane bandwidth} = \text{number of ports} \times \text{port rate} \times 2$ Backplane bandwidth, or switching bandwidth, is the maximum data throughput that can occur between a switch's interface processor or card and its data bus. Represented in gigabits per second (Gbps), this parameter determines the total data exchange capacity of a switch. Acting like a “highway”. The H3C S7500 Series switch deploys Salience TM III series engines with maximum switching capacity 768Gbps, with throughput as much as 432Mpps, while the backplane capacity reach 1. Here we choose a layer three network architecture, network structure for the access layer aggregation layer and core layer. Given that all port communications pass through the.
