

# Driving principle of three-legged laser diode

## Overview

The working principle of a laser diode is based on stimulated emission and population inversion within a forward-biased semiconductor p-n junction. When sufficient current flows, more electrons occupy the excited state than the ground state (population inversion). Much of what will be discussed will be in general terms of laser diode performance, warnings, and tips. The wavelength of emission is primarily determined by. This chapter starts with a brief recap of the fundamental aspects and elements of diode lasers, including relevant features of the standard device types, with an emphasis on the advantages of quantum heterostructures for their effective use as active regions in the lasers. Unlike conventional light-emitting diodes (LEDs), which produce broad-spectrum, incoherent light, the laser diode generates an intense beam at a single. A laser diode is a semiconductor device that emits coherent light through the process of stimulated emission.
