

Optical power meters become inaccurate after prolonged use

Overview

For absolute power, calibration is the biggest source of errors. Power meters are usually calibrated at 850 nanometers (nm), 1,300 nm and 1,550 nm, the three most common light wavelengths. Finding ways to optimize the performance of test equipment is one of the primary issues for managers, yet maintaining a large inventory of test and measurement equipment requires a systematic and efficient approach. This makes regular calibration of test and measurement equipment one of the most. Since optical fiber power meters (OFPMs) are a very common type of optical test equipment, NIST has developed and implemented measurement services to help characterize these instruments. 1 These measurement services consist of absolute power calibrations using either parallel-beam or optical. The accuracy of this equipment depends largely on the calibration quality of the power meters.
