

Relay protection for transformer parallel operation

Overview

87N high-impedance protection requires special class $\times$ current transformer cores with equal transformation ratios. The 7SJ60 relay can alternatively be connected in series with the 7UT613 relay to save this CT core. Earth faults on the secondary side are detected by current relay 51N. However, it has to be time-graded against downstream feeder protection relays. Primary circuit-breaker and relay may be replaced by fuses. Go back to contents ↑ Relay 7UT612 provides numerical ratio and vector group adaptation. Matching transformers as used with traditional relays are therefore no longer applicable. Line CTs are to be connected to separate stabilizing inputs of the differential relay 87T in order to ensure stability in the event of line through-fault currents. Relay 7UT613 provides numerical ratio and vector group adaptation. Go back to contents ↑ The directional functions 67 and 67N do not apply for cases where the transformers are equipped with the transformer differential relays 87T. Go back to contents ↑.
