

# What are the grounding requirements for electrical distribution boxes in Europe

## Overview

In the US, grounding and bonding are regulated by the National Electrical Code (NEC), while in the UK and Europe, they are guided by standards issued by the International Electrotechnical Commission (IEC) and national regulations such as BS 7671 (IET Wiring Regulations). The grounding system provides a low-impedance path for fault current and limits the voltage rise on the normally non-current-carrying metallic components of the electrical distribution system. During fault conditions, low impedance results in high fault current flow, causing overcurrent protective. Earthing/grounding systems connect specific parts of an electric power system, typically the equipment's conductive surface, with the ground for safety and functional purposes. “Earthing” is used in European countries, whereas “grounding” is used in North America and other countries worldwide. Whether you're a homeowner, an electrician, or an engineer, understanding the principles of grounding and bonding can help ensure that electrical systems are not only efficient but also safe from. The LPS designer and the LPS installer should select suitable types of earth electrodes and should locate them at safe distances from entrances and exits of a structure and from the external conductive parts in the soil, such as cables, metal ducts, etc. Today, we're diving deep into the world of distribution box grounding, breaking down the standards. It is a requirement of the Health and Safety at Work Act 1974, and the Electricity at Work Regulations 1989 that all persons carrying out electrical work must be competent to do so. The term 'skilled person' is used throughout BS 7671:2018, they are different terms, but they all mean the same.
